Q1-a-Parameters-Estimation

Fit the 1PL, 2PL, and 3PL models...report the estimated item parameters in separated tables

My Solution:

To make the layout concise and good-looking, I intentionally omitted the codes for data cleaning and some instant display of running outcomes. I attached the estimated item parameters from all three models into one table to save space.

```
Iteration: 1, Log-Lik: -20276.377, Max-Change: 0.18304Iteration: 2, Log-Lik: -20265.381, Max-Change: 0.
Calculating information matrix...
> irt_1pl
Call:
mirt(data = df, model = spec, itemtype = "2PL", SE = T)
Full-information item factor analysis with 1 factor(s).
Converged within 1e-04 tolerance after 25 EM iterations.
mirt version: 1.40
M-step optimizer: BFGS
EM acceleration: Ramsay
Number of rectangular quadrature: 61
Latent density type: Gaussian
Information matrix estimated with method: Oakes
Second-order test: model is a possible local maximum
Condition number of information matrix = 50.40657
Log-likelihood = -20260.22
Estimated parameters: 66
AIC = 40588.44
BIC = 40756.74; SABIC = 40648.75
> # -----
> #
                        Run 2PL
> irt_2pl <- mirt(df, model = 1, itemtype = "2PL", SE=T)</pre>
Iteration: 1, Log-Lik: -20276.377, Max-Change: 0.63072Iteration: 2, Log-Lik: -20095.717, Max-Change: 0.

Due to the limitation of mirt package, I can't constrain all the α to be 1. Rather, I can only set them to be equal across all the items. Therefore, in the estimation for the 1PL, the estimated universal α is .96 here.

Q1-a-(1)

Does it appear reasonable to assume all the items having an equal slope...

My Solution:

No.

From a aspect of test development, since this is a test about math placement, we should expect that items can discriminate students with different traits well. In addition, comparing the estimated parameters from 2PL model versus 1PL, these items' levels of discrimination spread along a wide range. It is reasonable to have items with higher levels of discrimination than others.

From a mathematics perspective, since the 1PL model is nested in the 2PL model, I conducted the Likelihood Ratio Test to compare the two models as followed:

$$D = -2[ln(L_{1pl}) - ln(L_{2pl})].$$

Plug the log likelihood estimated from the above code chunck, then one can have D = 363.2 at the degree of freedom of $df = df_{2pl} - df_{1pl} = 66 - 34 = 32$. Based on the Chi-squared distribution, the p value is lower than .001. Therefore, 2PL is better than 1PL, which means the discrimination is preferred.

Q1-a-(2)

Does it appear useful to include a guessing parameter in the model...

My Solution:

Yes, it is useful.

Intuitively, it is reasonable to include a guessing parameter since this a test with multiple choice and guessing is very possible. In addition, by looking through all the guessing parameters, one can find that the matchc13, matchc21, and matchc32 do have quite high guessing rate, i.e., all above .30.

However, in terms of model comparison, when using the LRT test again to compare the 2PL vs 3PL model, one can have D = 28.28 at 33 degree of freedom, P = .701. Based on the parsimony rule, one should endorse the simpler model, i.e., the 2PL.

Therefore, my overall conclusion is including a guessing parameter is useful in this scenario. A practitioner should choose the either model based on their purpose since these two models do not differ a lot.

Q1-a-(3)

Evaluate the goodness of fit of the items with the option of the chi-square test...

My Solution:

I conduct the item fit analysis on each model and summarize the results into one table to make the layout concise.

```
> # get the item fit indices for each model
> item_fit_1pl <- itemfit(irt_1pl, na.rm = T)</pre>
> item_fit_2pl <- itemfit(irt_2pl, na.rm = T)</pre>
> item_fit_3pl <- itemfit(irt_3pl, na.rm = T)</pre>
> # combine all the outputs into one table
 item_fit_all <- cbind(item_fit_1pl[,c("item")],</pre>
                        round(item_fit_1pl[,c("S_X2", "p.S_X2")],4),
                        round(item_fit_2pl[,c("S_X2", "p.S_X2")],4),
                        round(item_fit_3pl[,c("S_X2", "p.S_X2")],4))
 names(item fit all)[1] <- "item"</pre>
> # get all the item fit indices for 1PL, 2PL, and 3PL model
> item_fit_all
               S_X2 p.S_X2
                              S_X2 p.S_X2
                                              S_X2 p.S_X2

```

Past studies have recommended that a TLI of or above .95, a CFI of or above .95, an RMSEA of or below .05, and an SRMR of or below .05 could indicate a very good fit. Based on those criteria, all three model demonstrate very good model fit.

Next, by conducting the Likelihood Ratio Test (LRT) on 1PL vs. 2PL and 2PL vs. 3PL (finished in Q1-a-(1) and Q1-a-(2)), 2PL is preferred since it is significantly different from 1PL. In addition, LRT shows there is no significant difference in 2PL and 3PL. Based on the parsimony rule, I prefer 2PL model on this data.

Q1-a-(5)

Using the estimates obtained from the model you choose in part...

My Solution:

In the selected 2PL model, match: 28 shows the highest level of discrimination with $\alpha = 1.949$, and match: 35 has the lowest level of discrimination.

Next, to find the most informative item on a given trait level, I write a function that automatically search for the targeted item.

```
> # write a function to find the most informative item for a given trait
> most_info <- function(irt_model, trait){</pre>
    # irt_model can be any estimated IRT model
    # trait can be any given trait level
    a <- 0
    item num <- 0
   for (i in 1:33){
      # extract the item information at a given trait
      info_temp <- iteminfo(extract.item(irt_model, i), trait)</pre>
      # dynamically updated the best target
      if (info temp > a){
+
        a <- info_temp
        item num <- i
+
      }
+
    }
    out <- list(item_num = item_num,</pre>
                 info_value = a)
+
    return(out)
+ }
```

Then, I applied this function to find the most informative items on the given trait levels of $\theta = -1.5$, $\theta = 0$, and $\theta = 1.5$.

As shown above, the most informative item on $\theta = -1.5$ is the item matchc9. The most informative item on $\theta = 0$ is the item matchc28. The most informative item on $\theta = 1.5$ is the item matchc36.

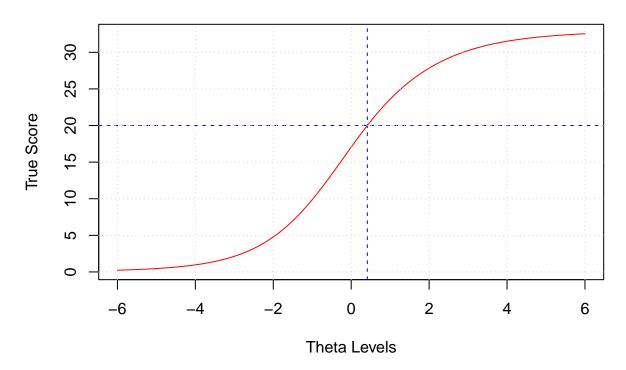

Q1-b

Using the estimates obtained from the model you choose in part...

My Solution: As discussed above, I used the 2PL model to conduct the analysis. First, I got all the expected score (i.e., true score) for each trait levels using the expected.test() function. Second, I located the trait score with a corresponding true score 20.

```
> # get the thetas from this sample
> theta <- fscores(irt_2pl, method = 'EAP')</pre>
>
 # re-define a vector of trait levles
>
 theta_tempt \leftarrow as.matrix(seq(-6,6,0.01))
> # find the trait level who have the true score of 20
> tscore <- expected.test(irt 2pl, theta tempt)</pre>
> theta_20 <- mean(theta_tempt[tscore >19.9 & tscore <20.1])
 # plot the TCC curve!
 plot(theta_tempt, tscore, type = "1", col="red",
       xlim = c(-6,6),
       main="Total Expected Score (i.e., TCC)",
       xlab="Theta Levels", ylab="True Score")
> abline(h = 20,col="blue",lty=2)
> abline(v = 0.413,col="blue",lty=2)
> grid()
```

Total Expected Score (i.e., TCC)

The TCC curve shows that the trait level of true score 20 is 0.41. Therefore, we need to select 10 items to have the maximum information on the 0.41.

Next, I try to get the information values of each item on 0.41 and sort these values in decreasing order. Finally, select the first ten items to make the shorter test.

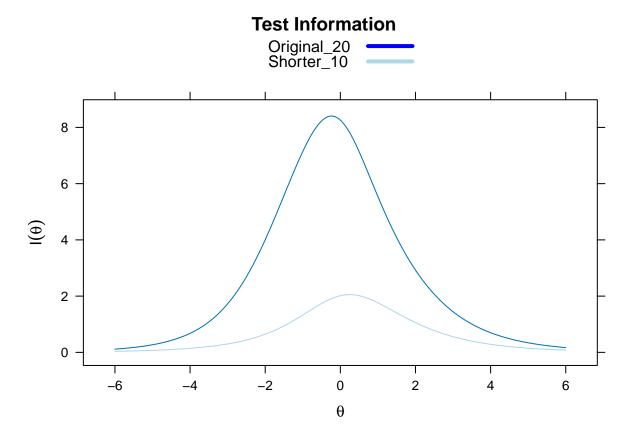

```
> info_set <- c()</pre>
> # using a for loop to get all info value at this given trait
> for (i in 1:33) {
  info_tempt <- iteminfo(extract.item(irt_2pl, i), theta_20)</pre>
  info_set[i] <- info_tempt</pre>
+ }
> # make a new df
> info matrix <- data.frame(</pre>
+ item = item_fit_2pl[,c("item")],
  info_value = info_set
+ )
> # sort this df in decreasing order
> info_matrix <- info_matrix[order(-info_matrix$info_value),]</pre>
> # get the first 10 items
> info_matrix[c(1:10),]
      item info_value
26 mathc28 0.7855788
25 mathc27 0.4398556
30 mathc33 0.3991881
3 mathc3 0.3752177
27 mathc29 0.3633219
4 mathc4 0.3375869
23 mathc25 0.3359483
6 mathc6 0.3034735
17 mathc18 0.2993334
10 mathc11 0.2719404
```

As shown above, I will select these ten items to create a shorter version of test.

```
> df_short <- df[,which(names(df) %in% info_matrix$item[1:10])]</pre>
> # fit 2PL on this short test
> irt_2pl_short <- mirt(df_short, model = 1, itemtype = "2PL", SE=T)</pre>
Iteration: 1, Log-Lik: -6666.931, Max-Change: 0.24246Iteration: 2, Log-Lik: -6639.237, Max-Change: 0.14
Calculating information matrix...
> irt_2pl_short
Call:
mirt(data = df_short, model = 1, itemtype = "2PL", SE = T)
Full-information item factor analysis with 1 factor(s).
Converged within 1e-04 tolerance after 16 EM iterations.
mirt version: 1.40
M-step optimizer: BFGS
EM acceleration: Ramsay
Number of rectangular quadrature: 61
Latent density type: Gaussian
Information matrix estimated with method: Oakes
Second-order test: model is a possible local maximum
Condition number of information matrix = 7.242151
Log-likelihood = -6629.432
```

```
Estimated parameters: 20
AIC = 13298.86
BIC = 13397.82; SABIC = 13334.3
```

Now to get the person trait estimation.

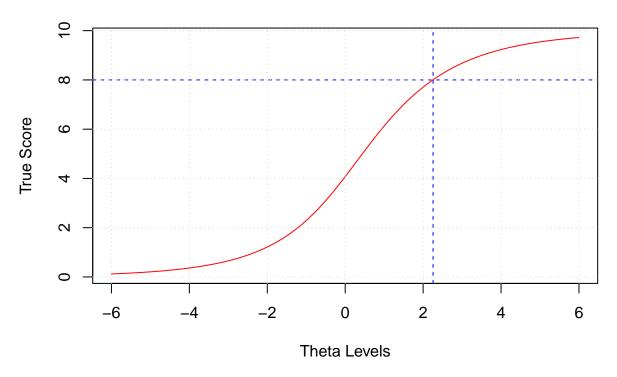

The plot shows that the peak of shorter test's information is closer to the target trait level 0.41. However, it provides less information comparing to the original 20 items test, which means shorter test is less accurate on estimating the given trait level comparing the to the original 20 items.

Q1-c

Assume a student with a true score of 8 on the ...

My Solution:

Total Expected Score (i.e., TCC) for Short Test

The plot shows that the corresponding trait level is around 2.255. Next, I extract the information at this level and calculate the standard error.

```
> # get the test info at the theta = 2.255
> test_info <- testinfo(irt_2pl_short, theta_tempt)
> info_8 <- test_info[theta_tempt == round(theta_8,2)]
>
> # calculate the SE based on the relation between the Info and SE
> se_8 <- 1/ sqrt(info_8)
> se_8
[1] 1.052787
```

Based on the all the calculation above, for a student with true score of 8, his/ her corresponding trait level for this short test is 2.255 with standard error 1.053.
